SORTING

Instructor: UĞUR HALICI

SORTING

We need to do sorting for the following reasons :

- a) By keeping a data file sorted, we can do binary search on it.
- b) Doing certain operations, like matching data in two different files, become much faster.

Given a file having n elements (records), there are various sorting methods, having different best and worst case behaviours.

	Best	Worst
Bubble sort	$\Omega(n^2)$	$O(n^2)$
Insertion sort	$\Omega(n^2)$	$O(n^2)$
Quick sort	$\Omega(n \log n)$	$O(n^2)$
Merge sort	$\Omega(n \log n)$	$O(n \log n)$

1. SELECTION SORT

- n data items are stored in Array A
- Make $n-1$ passes over the list
- On pass 0:
 - select the smallest element in the list
 - exchange it with $A[0]$
 - Front of the list $A[0]$ is ordered
 - Tail of the list $A[1]$ to $A[n-1]$ is unordered
- On pass 1:
 - select the smallest element in the unordered tail list
 - exchange it with $A[1]$
- Continue until $n-1$ passes

```

template <class T>
void SelectionSort(T A[ ], int n)
{// index of smallest item in each pass
    int smallIndex;
    int i, j;
// sort A[0]..A[n-2], and A[n-1] is in place
    for (i = 0; i < n-1; i++)
    {
        // start the scan at index i; set smallIndex to i
        smallIndex = i;
        // j scans the sublist A[i+1]..A[n-1]
        for (j = i+1; j < n; j++)
            // update smallIndex if smaller element is found
            if (A[j] < A[smallIndex]) smallIndex = j;
        // when finished, place smallest item in A[i]
        Swap(A[i], A[smallIndex]);
    }
}

template <class T>
void Swap (T &x, T &y)
{ T temp;
    temp = x; x = y; y = temp;}

```

A	0	1	2	3	4
init	5	4	3	2	1
i=0	1	4	3	2	5
i=1	1	2	3	4	5
i=2	1	2	3	4	5
i=3	1	2	3	4	5
i=4	1	2	3	4	5

A	0	1	2	3	4
init	12	7	5	2	6
i=0	2	7	5	12	6
i=1	2	5	7	12	6
i=2	2	5	6	12	7
i=3	2	5	6	7	12
i=4	2	5	6	7	12

$O(n^2)$, $\Omega(n^2)$, so $\Theta(n^2)$

2) BUBBLE SORT

- Array A with n elements
- n-1 passes
- Each pass,
 - we compare the adjacent elements

If $A[i-1] > A[j]$, the order is not correct and we exchange the elements

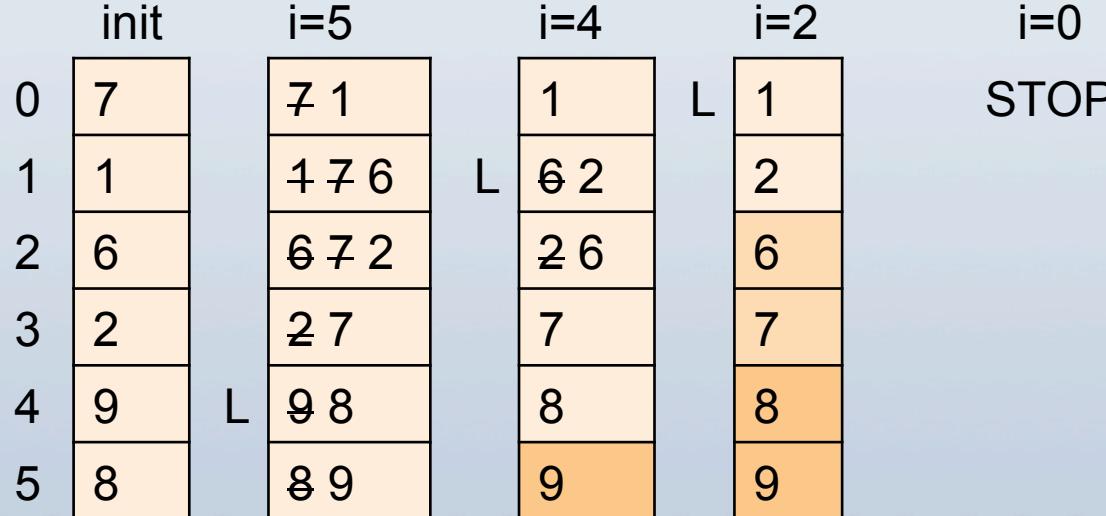

At the end of each pass: the largest element goes bottom of the current list, and smaller elements bubbles up towards top

- After pass 0 is complete: the tail of the list $A[n-1]$ is ordered and the front of the list remains unordered
- We keep track of the index of the last exchanged element

```

template <class T>
void BubbleSort(T A[], int n)
{ int i,j;
  int lastExchangeIndex;
  i = n-1; // i is the index of last element in the sublist
  // continue the process until no exchanges are made
  while (i > 0)
  { lastExchangeIndex = 0;
    // scan the sublist A[0] to A[i]
    for (j = 0; j < i; j++)
      // exchange a pair and update lastExchangeIndex
      if (A[j] > A[j+1]) { Swap(A[j],A[j+1]); lastExchangeIndex = j; }
    // set i to index of the last exchange. continue sorting the sublist A[0] to A[i]
    i = lastExchangeIndex;
  }
}

```

3) QUICK SORT

Partition approach to sort a list

Main Idea:

- Determine a pivot value
- Split the list into two parts according to the pivot
- Items smaller than the pivot goes into sublist left : sL
- Items larger than the pivot goes into right sublist: sR
- For sL and sR repeat the same procedure

	0	1	2	3	4	5	6	7	8	9
A	55	15	30	60	80	65	40	35	45	70

Scanning phase:

Low index: low=0

High index: high=9

The pivot: A[low]=55

we scan the entire list A[low+1] to A[9]

2 sublists : sL ≤ pivot, sR > pivot

- Two index variables: iL and iR
- iL : responsible for locating the elements in sublist sL
Initially: iL is set as $low+1=1$
- iR : responsible for locating the elements in sublist sR
Initially: iR is set as $high=9$
- Each pass identifies the elements in each of the sublists

- Each pass identifies the elements in each of the sublists
- iL searches the left list. It moves right as far as $A[iL] \leq \text{pivot}$
- iR searches the right list. It moves left as far as $A[iR] > \text{pivot}$

	0	1	2	3	4	5	6	7	8	9
A	55	15	30	60	80	65	40	75	45	70

$iL=3; A[3]=60>55$

$iR=8; A[8]=45<55$

- Those two elements are in wrong sublists so exchange them: $\text{Swap}(A[iL], A[iR])$

	0	1	2	3	4	5	6	7	8	9
A	55	15	30	45	80	65	40	75	60	70

	0	1	2	3	4	5	6	7	8	9
L1: A	55	15	30	60	80	65	40	75	45	70
L1: A	55	15	30	45	80	65	40	75	60	70
L1: A	55	15	30	45	40	65	80	75	60	70
L1: A	55	15	30	45	40	65	80	35	60	70
L1: A	40	15	30	45	55	65	80	35	60	70

Continue until iL and iR pass each other

iR separates the list, Put Pivot back in its place:

Swap(A[low], A[iR])

then sL=A[0]-A[4], sH=A[6]-A[9]

- Recursive phase:

	0	1	2	3	4	5	6	7	8	9
L1: A	40	15	30	45	55	65	80	35	60	70
P										

Apply the algorithm

L2: sL	40	15	30	45	55	65	80	35	60	70
--------	----	----	----	----	----	----	----	----	----	----

- Use recursion to process the sublists:

- choose first element as pivot to split the list
- Recursive part Call with parameters for

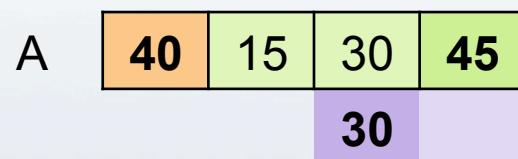

L2: sR	40	15	30	45	55	65	80	35	60	70
--------	----	----	----	----	----	----	----	----	----	----

- 300,150,400,450,350
- ScanUp=400:A[2]
- ScanDown=150:A[1]
- Halt the process
- Exchange pivot and ScanDown
- 150,300,400,450,350
- Stop processing SI because it is single element

- Recursive phase: Level 2, sL

$A=sL$: low=0, high=3, pivot= $A[low]=40$

	0	1	2	3	4	5	6	7	8	9
L2: A	40	15	30	45	55	65	80	35	60	70

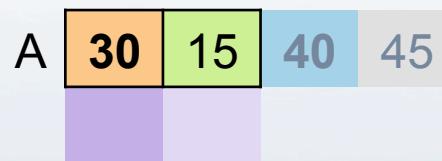

L3: sL	30	15	40	45
--------	----	----	----	----

L3: sR	30	15	40	45
--------	----	----	----	----

- Recursive phase: Level3, sL

A=sL: low=0, high=1 pivot=A[low]=30

Recursive phase: Level4, sL: 1 element, return back

Recursive phase: Level4, sR: 0 element, return back

Recursive phase: Level3, sR: 1 element, return back

- Recursive phase: Level 2: sR

$A=sR$: low=5, high=9 pivot= $A[low]=65$

	0	1	2	3	4	5	6	7	8	9
L2: A	15	30	40	45	55	65	80	35	60	70

A	65	60	35	80	70
---	----	----	----	----	----

A	65	60	35	80	70

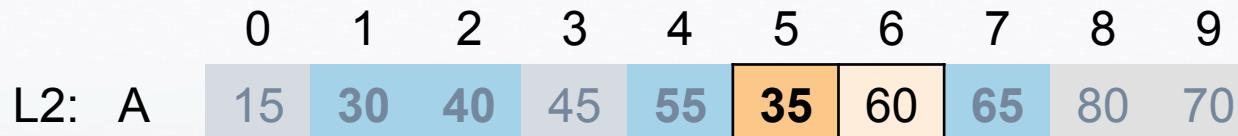

A	35	60	65	80	70
---	----	----	----	----	----

L3: sL	35	60	65	80	70
--------	----	----	----	----	----

L3: sR	35	60	65	80	70
--------	----	----	----	----	----

- Recursive phase: Level 3: sL

A=sL: low=5, high=6 pivot=A[low]=35

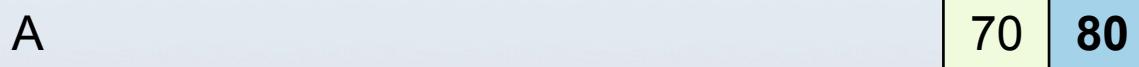

Recursive phase: Level4, sL: 0 element, return back

Recursive phase: Level4, sR: 1 element, return back

- Recursive phase: Level 2: sR

$A=sR$: low=8, high=9 pivot= $A[low]=80$

	0	1	2	3	4	5	6	7	8	9
L2: A	15	30	40	45	55	35	60	65	80	70

Recursive phase: Level3, sL: 1 element, return back

Recursive phase: Level3, sR: 0 element, return back

- summary: at the end of each level we will have sL and sR as:

	A	0	1	2	3	4	5	6	7	8	9
init		55	15	30	60	80	65	40	75	45	70
L1:		40	15	30	45	55	65	80	35	60	70
L2:		30	15	40	45	55	35	60	65	80	70
L3		15	30	40	45	55	35	60	65	70	80
L4:		15	30	40	45	55	35	60	65	70	80
final		15	30	40	45	55	35	60	65	70	80

```
Template <classT>
void qsort(T *A, int low, int high)
{//quick sort
    if (low<high) {
        int iL=low+1;
        int iR=high;
        T pivot=A[low];
        while (True)
        {   while (A[iL] <=elem) {iL++};
            while (A[iR] >elem) {iR--};
            if (iL<iR)
                swap(A,iL,iR);
            else break;
        }
        swap(A,low,iR);
        qsort(A,low,iR-1);
        qsort(A, iR+1,high);
    }
}
```

4. RADIX SORT

20

Let's have the following 4-bit binary numbers. Assume there is no sign bit.

1	0	1	0
0	1	0	1
0	0	1	1
1	0	1	1
0	1	1	0
0	1	1	1

(10)
(5)
(3)
(11)
(6)
(7)

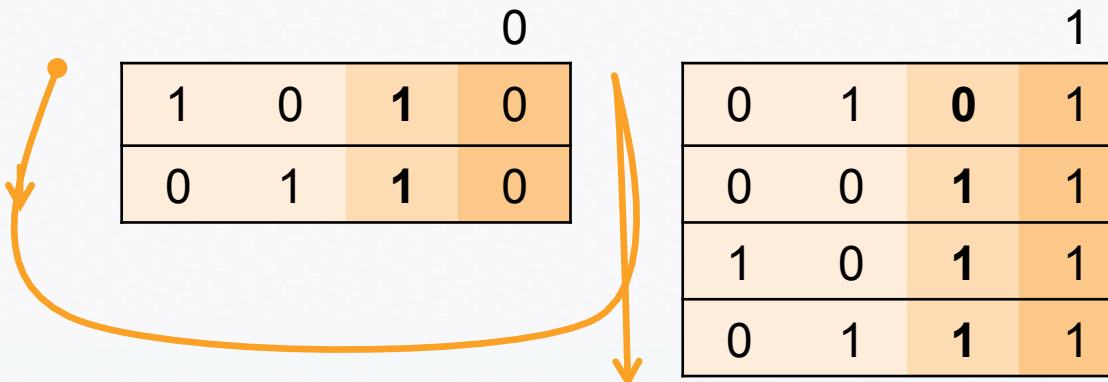

- 1) First begin with the LSB (least significant bit). Make two groups, one with all numbers that end in a "0" and the other with all numbers that end in a "1".

0

1	0	1	0
0	1	1	0

1

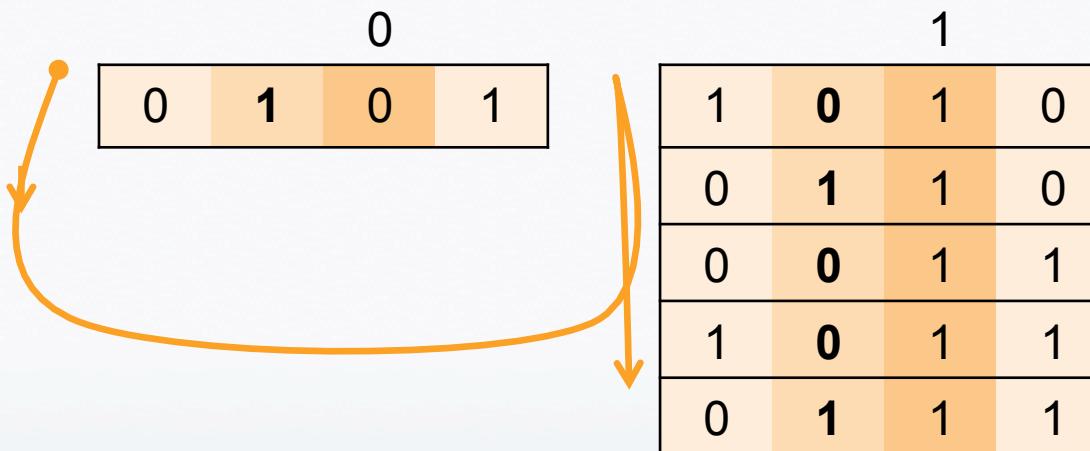

0	1	0	1
0	0	1	1
1	0	1	1
0	1	1	1

- 2) Now, go to the next less SB and by examining the previous groups in order, form two new groups:

		0	
0	1	0	1

		1	
1	0	1	0
0	1	1	0
0	0	1	1
1	0	1	1
0	1	1	1

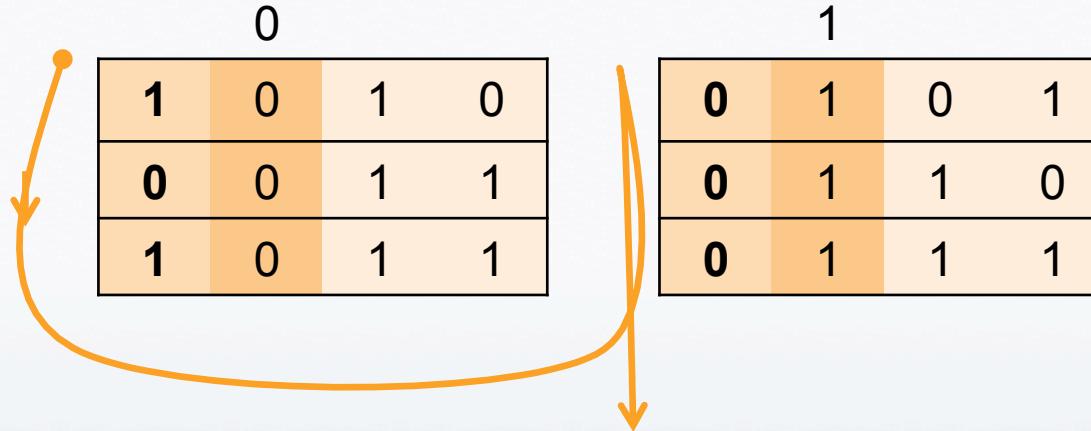

3) Repeat the operation for the third bit from the right:

A diagram illustrating a memory operation. Two 4-bit arrays are shown. The first array has a 0 above it, and the second array has a 1 above it. Both arrays have their third bits highlighted in orange.

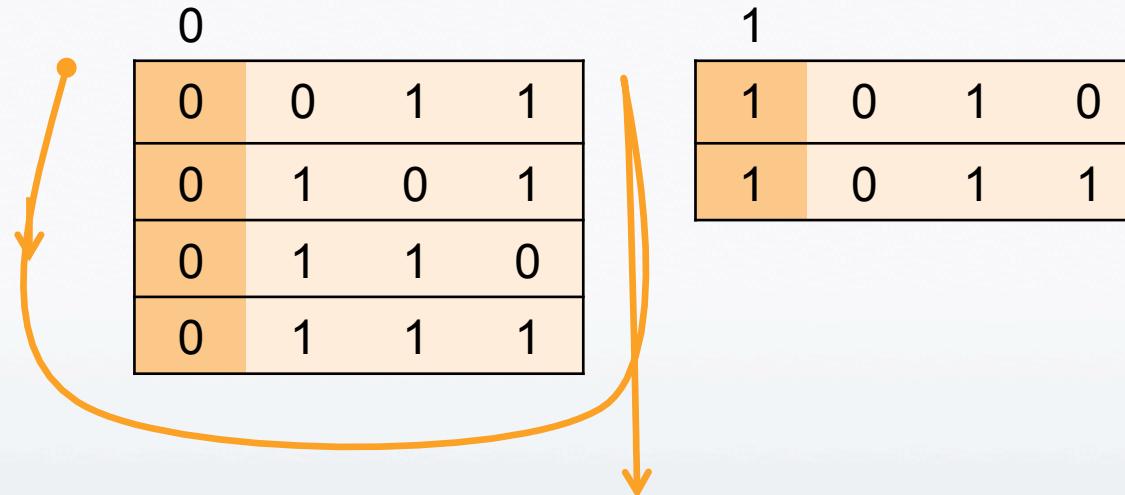

1	0	1	0
0	0	1	1
1	0	1	1

0	1	0	1
0	1	1	0
0	1	1	1

4) Repeat it for the most significant bit:

0	1
0 0 1 1	1 0 1 0
0 1 0 1	1 0 1 1
0 1 1 0	
0 1 1 1	

Then the result is

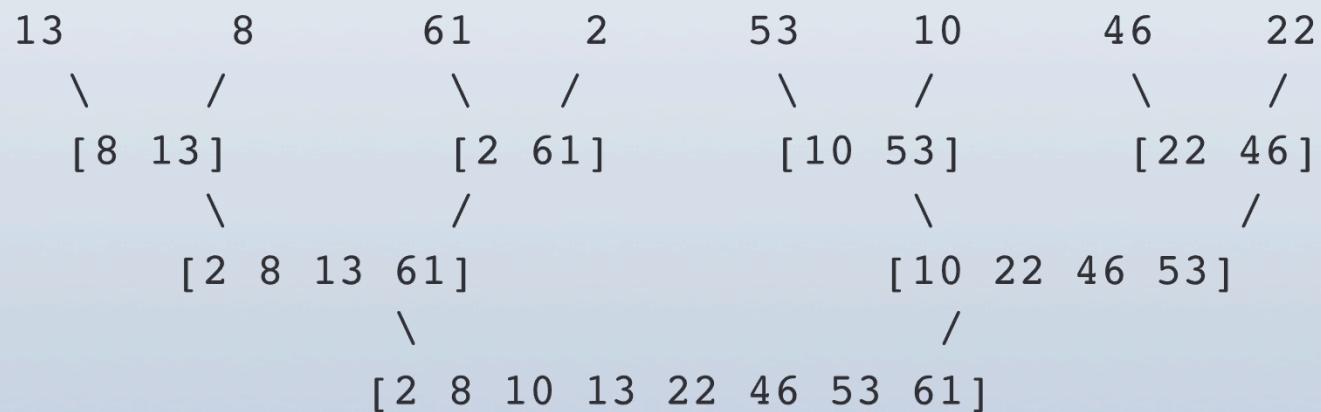

0	0	1	1	(3)
0	1	0	1	(5)
0	1	1	0	(6)
0	1	1	1	(7)
1	0	1	0	(10)
1	0	1	1	(11)

5. MERGE

In merge sort, two already sorted files are 'merged' to obtain a third file which is the sorted combination of the two sorted input files.

- We begin by assuming we have n sorted files with size=1
- Then, we merge these files of size=1 pairwise to obtain n/2 sorted files of size=2
- Then, we merge these n/2 files of size=2 pairwise to obtain n/4 sorted files of size=4, etc..
- Until we are left with one file with size=n.

Example :

To merge two sorted files ($x[1]..x[m]$) and ($y[1]..y[n]$), to get a third file ($z[1]..z[m+n]$) with $key_1 < key_2 < \dots < key_n$, which will be the sorted combination of them, the following procedure can be used :

```

int MERGE(m,n:integer; int x[ ], int
y[ ]; int &z[ ]);
int i,j,k,p
{i=1; /* i is a pointer to x */
 j=1; /* j is a pointer to y */
 k=1;
/* k points to the next available
location in z */
while (i<=m)&& (j<=n)
{
    if (x[i].key <= y[j].key)
    { /* take element from x */
        z[k]=x[i];
        i++;
    }
    else
    { /* take element from y */
        z[k]=y[j];
        j++;
    }
}

```

```

k:=k+1
/* added one more element into z */
}; /* while */
if ( i>m )
{
    for (p=j;p<=n; p++)
        z[k++]= y[p]
    /* remainig part of y into z */
}
else
{
    for (p=i; j<=m; j++)
        z[k++] = x[p]
    /* remaining part of x into z */
}
return k-1;
}

```
